# Session 1 Introduction to R

Shakiba Baharvand

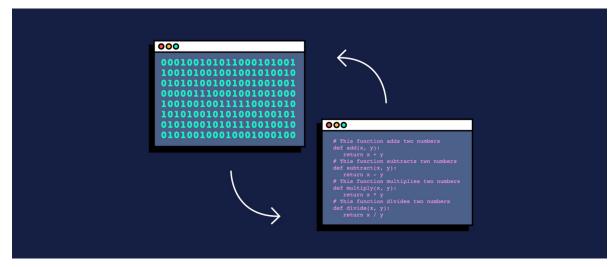

2022-08-29

# Introduction to the Workshop

This workshop is for biologists interested in learning how to work with R to analyse their bulk RNA-seq data and perform pathway analysis. This will be a code-along, in-person workshop.

# What is Programming?

Programming is giving a set of instructions to a computer to perform tasks. Programming can be done using a variety of computer programming languages. Programming languages are the tools we use to write computer instructions. Computers only understand 1s and 0s. 0s mean no flow of electricity, and 1s represent electricity is allowed to flow. Programming languages allow us to translate 1s and 0s into something humans can understand.

# R as a Programming Language

R is both software and language. R is a system for statistical analyses and graphics. At first, R could seem too complex for a non-specialist. This may not be true. R's syntax is straightforward.

```
library(tidyverse)

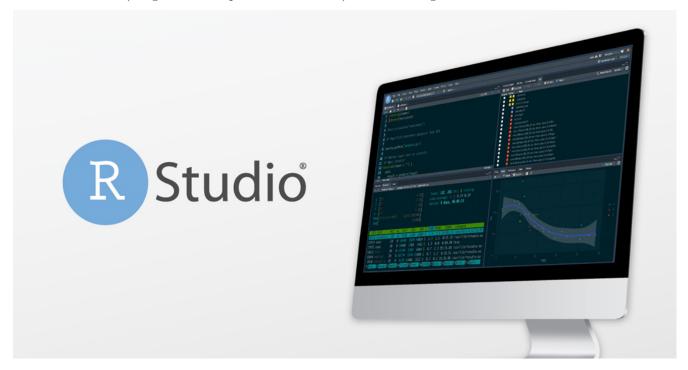

urchins <- read_csv("https://tidymodels.org/start/models/urchins.csv") %>%
    setNames(c("food_regime", "initial_volume", "width")) %>%
    mutate(food_regime = factor(food_regime, levels = c("Init", "Low", "High")))

urchins %>%
    group_by(food_regime) %>%
    summarise(
    across(everything(), mean), n = n()
)

mean(urchins$width)
ggplot2::cut_interval(urchins$initial_volume)
```

## **RStudio**

RStudio is an IDE (integrated development environment) used to manage and execute R code.

## First line of code

Open RStudio and make an R script file.

Write: print("Hello, World!") Then, press ctrl + enter.

```
print("Hello, World!")

## [1] "Hello, World!"

> print("Hello, World!")

[1] "Hello, World!"

> |
```

You can see the phrase is presented on your console. When that little angle bracket is represented, it means there is no work in progress, and you can run a new instruction. But if you can't see the angle bracket, it means some instructions are running, and you need to wait.

The phrase "Hello, World!" is a small test which existed since the development of programmable computers. It is a tradition to use this phrase as a test message.

## Comments

Comments are used to document and explain the code. They are ignored when the program is running. A comment can be created using # (hash sign or number sign) in R.

```
# This is a comment!
# outputs "Hello, World!"
print("Hello, World!")
```

## [1] "Hello, World!"

## Variables

Every R program deals with data. Variables allow us to store and manipulate data. They have a name and value and are bound by an assignment operator.

We will discuss five main types of variables in R.

You can show the data type with the typeof() function. Also, class() show you the class an object belongs to.

# Type of variables

#### numeric

It represents all real numbers with or without decimal values.

```
num_var <- 1234</pre>
print(num_var)
## [1] 1234
typeof(num_var)
## [1] "double"
class(num_var)
## [1] "numeric"
integer It specifies real values without decimal points. You can define it with an L at the end of the
number.
int_var <- 11L</pre>
print(int_var)
## [1] 11
typeof(int_var)
## [1] "integer"
class(int_var)
## [1] "integer"
complex It is used to specify purely imaginary values.
comp_var <- 2-6i
print(comp_var)
## [1] 2-6i
typeof(comp_var)
## [1] "complex"
```

```
class(comp_var)
## [1] "complex"
character It is used to specify character or string values in a variable. You can define it by writing a text
in a couple of single or double quotations. A string is a set of characters. For example, "A" is a character
but "Hello1234!" is a string.
char_var <- "Hello, World!"</pre>
print(char_var)
## [1] "Hello, World!"
typeof(char_var)
## [1] "character"
class(char_var)
## [1] "character"
logical They are binary values, which can be True or False.
log_var <- TRUE</pre>
print(log_var)
## [1] TRUE
typeof(log_var)
## [1] "logical"
class(log_var)
## [1] "logical"
log_var <- FALSE</pre>
log_var <- T</pre>
log_var <- F</pre>
Converting Between Variables
Converting between data types in R is possible with these functions.
   as.logical()
                                                                 as.integer()
                                                                                     as.complex()
```

as.character()

as.numeric()

```
var <- 22.84
as.integer(var)

## [1] 22
as.complex(var)

## [1] 22.84+0i
as.character(var)

## [1] "22.84"</pre>
```

# Missing data and NULL object

- The NA symbol represents missing values. (not available)
- The NaN symbol represents impossible values. (for example, dividing by zero) (not a number)
- NULL object in R is used to represent the undefined values. (We will discuss them more.)

## **Operators**

An operator is a symbol that tells the computer to perform specific actions. There are three main types of operators in R.

Arithmetic			Operators Comparison	Logical			
+ - * / ^ %%	addition subtraction multiplication division power modulo integer division	< > < > < = > = ! =	lesser than greater than lesser than or equal to greater than or equal to equal different	! x x & y x & y x   y x    y xor(x, y)	logical NOT logical AND id. logical OR id. exclusive OR		

Figure 1: R for Beginners, Emmanuel Paradis, page 29

```
a <- -3; b <- 10
# arithmatic
a + b
```

## [1] 7

```
b %% 3
## [1] 1
# comparison
a > b
## [1] FALSE

a == b
## [1] FALSE

a != b
## [1] TRUE
# logical
(a == b) & (a == -3)
## [1] FALSE

(a == b) | (a == -3)
## [1] TRUE
```

## **Functions**

Functions are a piece of code that accomplish a specific task. Functions usually take in some data, process it, and return a result. Functions are always recognisable with a pair of parenthesis.

As an example, as.integer() is a function. Its argument is a numeric variable, and it returns an integer value. It is recognisable by its parenthesis.

# var\_integer <- as.integer(var\_numeric)

Some functions are in-built in R or provided by the packages. (Packages are the collection of R functions.) Also, you can write your own function. We will discuss it later.

Here is a list of maths functions of base R. You can find helpful functions from base R in the book of R for Beginners by Emmanuel Paradis on pages 36 and 37.

# **Maths Functions**

log(x)	Natural log.	sum(x)	Sum.
exp(x)	Exponential.	mean(x)	Mean.
max(x)	Largest element.	median(x)	Median.
min(x)	Smallest element.	quantile(x)	Percentage quantiles.
round(x, n)	Round to n decimal places.	rank(x)	Rank of elements.
<pre>signif(x, n)</pre>	Round to n significant figures.	var(x)	The variance.
cor(x, y)	Correlation.	sd(x)	The standard deviation.

## **Conditional Statements**

Imagine you have a list of numbers and need to separate odd numbers from this list. We know that there is always a remainder when an odd number is divided by 2, which is not equal to zero. If you want to check the list, you can tell the computer to check if the remainder of the number nth in the list is not equal to zero. If it is, pick the nth number in the list. This phrase is a condition that the computer needs to check it. Conditional statements are the way computers can make decisions. Conditional statements always have an if part, and if you need more conditions to make up your decisions, the else part can be helpful.

```
if (Condition) {
        Do something
}
```

```
if (Condition) {
        Do something
} else {
        Do something
        different
}
```

```
if (Condition1) {
        Do something
} else if (Condotion2)
        Do something
        different
} else if (Condition3)
        Do something
        different
} else {
        Do something
        different
}
```

The below code shows how to pick odd numbers from the list of numbers. We've already learned the

remainder operator %%, and we know the conditional operates like==, !=, \<, \>\.

```
var <- 11
if (var %% 2 != 0) {
    print("the number is odd.")
}

## [1] "the number is odd."

if (var %% 2 == 0) {
    print("the number is even.")
} else {
    print("the number is not even")
}

## [1] "the number is not even"

if (var %% 2 == 0) {
    print("the number is even.")
} else if (var %% 11 == 0) {
    print("the number is the multiple of 11")} else {
        print("the number is odd.")
    }
}</pre>
```

## [1] "the number is the multiple of 11"

# Loops

In computer programming, a loop is a sequence of instructions that continually repeats until a certain condition is reached. For example, you want to print stars with a specific pattern. You have five lines. Line n should have n stars, first line one star, second line two stars and so on. You can make this output with a loop. There are two types of loops.

```
for ( variable in sequence) {
    Do something
}
```

```
while (condition) {
    Do something
}
```

```
n <- c(1:5) #n = (1, 2, 3, 4, 5) - n is a sequence
for (i in n) {
  print(rep("*", i)) #The `rep(value, x)` function replicates the values in x.
}</pre>
```

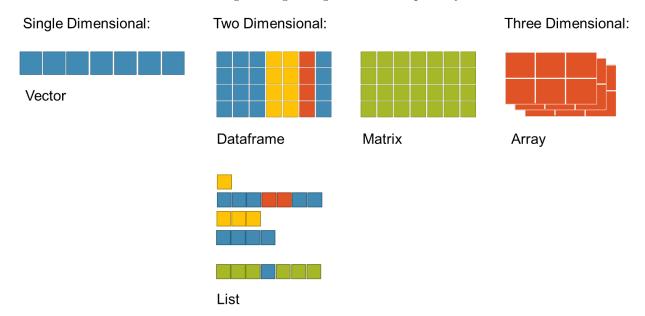

```
## [1] "*"
## [1] "*" "*"
## [1] "*" "*"
## [1] "*" "*" "*"
## [1] "*" "*" "*"
```

```
i <- 1
while (i <= 5) {
  print(rep("*", i))
  i <- i + 1
}</pre>
```

```
## [1] "*"
## [1] "*" "*"
## [1] "*" "*" "*"
## [1] "*" "*" "*" "*"
## [1] "*" "*" "*" "*"
```

## **Data Structures**

Data structures are methods of storing and organising data in a computer system.

## Vectors

A vector is just a set of objects of the same type.

## Creating

A vector can be created using the c(). There are different ways to create a vector. The below tables show them.

```
Join elements into
c(2, 4, 6)
                        2 4 6
                                            a vector
                                           An integer
                        2 3 4 5 6
2:6
                                           sequence
                                           A complex
seq(2, 3, by=0.5)
                        2.0 2.5 3.0
                                           sequence
rep(1:2, times=3)
                        1 2 1 2 1 2
                                         Repeat a vector
                                         Repeat elements
rep(1:2, each=3)
                        1 1 1 2 2 2
                                           of a vector
```

```
# join elements to a vector
names_vec <- c("Sarah", "Maria", "Alex")
names_vec</pre>
```

## [1] "Sarah" "Maria" "Alex"

```
# create an integer sequence
int_vec <- c(1:10)
int_vec</pre>
```

**##** [1] 1 2 3 4 5 6 7 8 9 10

```
# create a sequence of decimal numbers
dec_vec <- seq(from = 0, to = 2, by = 0.5)
dec_vec</pre>
```

## [1] 0.0 0.5 1.0 1.5 2.0

```
# create a vector with repeating elements
## repeats the whole x, n times
rep_t_vec <- rep(x = c(1:2), times = 3)
rep_t_vec</pre>
```

## [1] 1 2 1 2 1 2

```
## repeats each element in x, n times
rep_e_vec <- rep(x = c(1:2), each = 3)
rep_e_vec
## [1] 1 1 1 2 2 2
Q: Is it possible to store different types of variables in a vector?
It is possible, but the variables' types change after creating the vector.
# you can see the elements' types are changed to the character, and when we want to show them, you can
names_vec_2 <- c("Sarah", 2, TRUE)</pre>
class(names_vec_2[2])
## [1] "character"
names_vec_2[2]
## [1] "2"
class(names_vec_2[3])
## [1] "character"
names_vec_2[3]
## [1] "TRUE"
# you can see the elements' types are changed to numeric.
## logical values as numeric values: TRUE -> 1, FALSE -> 0
names_vec_3 <- c(TRUE, 2)</pre>
class(names_vec_3[1])
## [1] "numeric"
names_vec_3[1]
## [1] 1
class(names_vec_3[2])
## [1] "numeric"
names_vec_3[2]
## [1] 2
```

## Naming

You can name vector elements.

```
vec <- c(first = 10, second = 20, third = 30)</pre>
##
    first second third
               20
                       30
##
       10
If you already have a vector, there are two functions to use.
new_vec <- c(10, 20, 30)
new_vec <- setNames(vec, c("I", "am", "happy"))</pre>
new_vec
##
       Ι
             am happy
##
      10
             20
                   30
names(new_vec) <- c("sarah", "maria", "alex")</pre>
new_vec
## sarah maria alex
##
      10
             20
                    30
```

## **Selecting Elements**

You can select elements of a vector by position and value. We call the position of the index of the element.

В	y Position	By Value				
x[4]	The fourth element.	The fourth element. $x[x == 10]$ Element are				
x[-4]	All but the fourth.	x[x < 0]	All elements less than zero.			
x[2:4]	Elements two to four	x[x %in% c( <mark>1, 2, 5</mark> )]	Elements in the set 1, 2, 5.			
x[-(2:4)]	All elements except two to four.	Name	ed Vectors			
x[c(1, 5)]	Elements one and five.	x['apple']	Element with name 'apple'.			

```
# by position
heroes_vec[2]
## [1] "batman"
heroes_vec[-2]
## [1] "spiderman" "joker"
                                "thor"
                                             "ironman"
heroes_vec[2:5]
## [1] "batman" "joker"
                            "thor"
                                       "ironman"
heroes_vec[-(2:5)]
## [1] "spiderman"
heroes_vec[c(1, 5)]
## [1] "spiderman" "ironman"
# by value
subset_vec <- c("joker", "ironman")</pre>
hero <- "batman"
heroes_vec[heroes_vec == hero] # you can put any other conditions here
## [1] "batman"
heroes_vec[heroes_vec %in% subset_vec]
## [1] "joker"
                  "ironman"
# named vector
names(heroes_vec) <- c("Marvel1", "Marvel2", "Marvel3", "Marvel4", "Marvel5")</pre>
heroes_vec['Marvel3']
## Marvel3
## "joker"
```

#### Order

You can order a vector with two functions. By default, these functions order a vector in ascending order. Syntax: sort(x, decreasing)

```
n <- c(12, 1, 133, -2)
## [1] 12 1 133 -2
n_sorted <- sort(n, decreasing = TRUE) #by setting the decreasing argument to TRUE, we can order the ve
n\_sorted
## [1] 133 12 1 -2
Syntax: order(x)
order(-n) #order() returns the ordered elements
## [1] 3 1 2 4
n_ordered <- n[order(-n)] #by putting a minus before the argument, we can order the vector descending
n_ordered
## [1] 133 12 1 -2
Combine Vectors
You can add a vector to others with c(). You can use it to add a new element, too.
# add a vector to another
x <- c("x1", "x2")
y \leftarrow c("y1", "y2")
combined\_vec \leftarrow c(x, y) \text{ # the order of vectors in c function is important}
combined_vec
## [1] "x1" "x2" "y1" "y2"
combined_vec <- c(y, x)</pre>
combined_vec
## [1] "y1" "y2" "x1" "x2"
# add a new element to a vector
x \leftarrow c(x, "hi!")
## [1] "x1" "x2" "hi!"
Length
You can show the length of a vector by length().
```

Syntax: length(x)

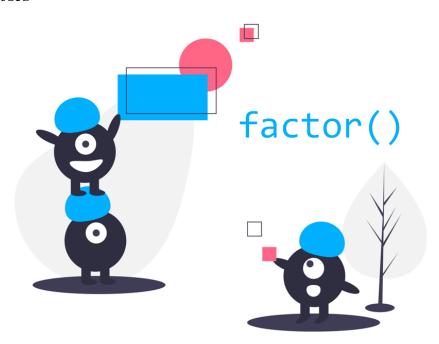

```
vec <- (1:10)
vec

## [1] 1 2 3 4 5 6 7 8 9 10

length(vec)</pre>
```

## [1] 10

#### **Factors**

Factors are used to represent categorical data. They are kind of ordered labelled vectors. Factors are an important class for statistical analysis and helpful in plotting. The factor() allows us to create factors.

 $Syntax: \ factor(x, \ levels)$ 

```
#factor()
cities_vec <- c("Vancouver", "Burnaby", "Tehran", "Vancouver", "Tehran")
cities_fac <- factor(x = cities_vec)
cities_fac

## [1] Vancouver Burnaby Tehran Vancouver

cities_fac <- factor(x = cities_vec, levels = sort(unique(cities_vec)))
cities_fac

## [1] Vancouver Burnaby Tehran Vancouver Tehran

## Levels: Burnaby Tehran Vancouver Tehran

## Levels: Burnaby Tehran Vancouver</pre>
```

```
# unique() returns a vector/data frame with duplicate elements/rows removed
# we know sort() from the last part. When you sort a vector of characters, it will sort it alphabetical
```

The factor is a type of data.

```
class(cities_fac)

## [1] "factor"

You can relevel your factor object or display it by levels(). Syntax: levels(x)

l_vec <- levels(cities_fac)
l_vec

## [1] "Burnaby" "Tehran" "Vancouver"

levels(cities_fac) <- rev(l_vec) # rev() reverses a vector
cities_fac

## [1] Burnaby Vancouver Tehran Burnaby Tehran
## Levels: Vancouver Tehran Burnaby</pre>
```

#### **Data Frames**

A data frame is the most common way of sorting data in R. It is a list of equal-length vectors. It is table shaped and has columns and rows.

Column names should not be empty in a data frame. Row names should be unique.

#### Creating

## 2 spiderman

You can create a data frame with data.frame()

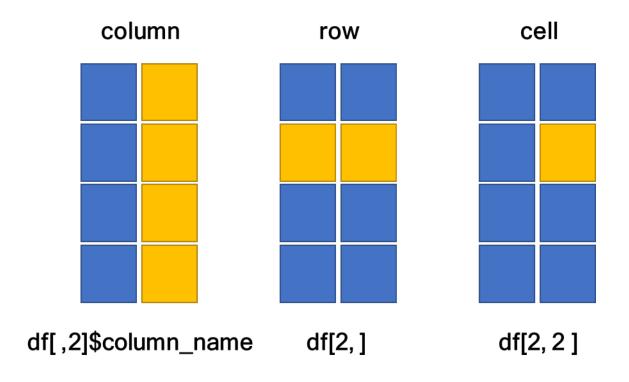

8.0

Syntax: data.frame(vec1, vec2, vec3, ...)

```
name strength_score
## hero_1 ironman 10.0
## hero_2 spiderman
                             8.0
## hero_3
                             8.2
            batman
# we can add a new column with the $ operator.
heroes_df$assigned_color <- c("red", "red&blue", "black")
heroes_df
##
              name strength_score assigned_color
## hero_1 ironman
                       10.0
## hero_2 spiderman
                            8.0
                                      red&blue
## hero_3
            batman
                             8.2
                                         black
```

#### Subsetting

## [1] 10.0 8.0 8.2

When we don't specify the row index or column index, we select all of them.

```
# column
heroes_df[, 1]

## [1] "ironman" "spiderman" "batman"
heroes_df$strength_score
```

#### **Functions**

nrow(df)

Numbers of rows

ncol(df)

Numbers of columns

dim(df)

Numbers of columns and rows

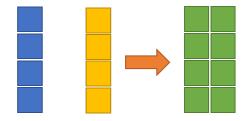

t(df)

Transpose

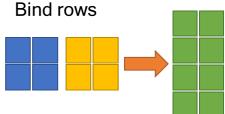

- colnames(df)
  - Name columns of a df
- rownames(df)

Name rows of a df

- str(df)
   display the internal structure
   of an object
- cbind(df1, df2)
   Bind columns

• rbind(df1, df2)

```
# R has some in-built data sets. You can load them by data("name of data set")
data("mtcars")
# display the internal structure
str(mtcars)
```

```
## 'data.frame': 32 obs. of 11 variables:
## $ mpg : num 21 21 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 ...
## $ cyl : num 6 6 4 6 8 6 8 4 4 6 ...
## $ disp: num 160 160 108 258 360 ...
```

```
## $ hp : num 110 110 93 110 175 105 245 62 95 123 ...
## $ drat: num 3.9 3.9 3.85 3.08 3.15 2.76 3.21 3.69 3.92 3.92 ...
## $ wt : num 2.62 2.88 2.32 3.21 3.44 ...
## $ qsec: num 16.5 17 18.6 19.4 17 ...
## $ vs : num 0 0 1 1 0 1 0 1 1 1 ...
## $ am : num 1 1 1 0 0 0 0 0 0 0 ...
## $ gear: num 4 4 4 3 3 3 3 4 4 4 ...
## $ carb: num 4 4 1 1 2 1 4 2 2 4 ...
## it shows that there are 11 columns with 32 elements in each column.
## All of the values in the columns are numeric. The mtcars is a data frame.
# column names and row names
col_names <- colnames(mtcars)</pre>
col_names
## [1] "mpg" "cyl" "disp" "hp" "drat" "wt"
                                                "qsec" "vs"
                                                                      "gear"
## [11] "carb"
## toupper() is a function to capitalise all of the letters in a string

```

#### Matrices

Matrix is a collection of elements of the same data type arranged into a fixed number of rows and columns. The length of columns should be equal.

#### Creating

You can create a matrix with matrix().

Syntax: matrix(x, nrow, ncol, byrow) The nrow and ncol arguments determine the number of rows and columns. The byrow argument accepts logical values. If it sets to TRUE, the matrix is filled by columns, otherwise is filled by rows.

```
vec \leftarrow c(1:10)
matrix(data = vec, nrow = 5, ncol = 2, byrow = FALSE)
##
         [,1] [,2]
## [1,]
            1
## [2,]
                  7
            2
## [3,]
            3
                  8
                  9
## [4,]
            4
## [5,]
            5
                10
matrix(data = vec, nrow = 5, ncol = 2, byrow = TRUE)
         [,1] [,2]
##
## [1,]
                  2
            1
## [2,]
            3
                  4
## [3,]
            5
                  6
## [4,]
            7
                  8
## [5,]
            9
                 10
```

The mentioned functions in the data frame part can be used for matrices.

## Lists

Lists are ordered collections of any R object. It stores different types of elements. Collections can have different lengths despite matrices and data frames.

#### Creating

## [2,]

2

7

You can create a list with the list(). Syntax: list(object1, object2, object3, ...)

```
vec <- c(1:10)
mat <- matrix(vec, nrow = 5, ncol = 2)
fac <- factor(c("blue", "red", "blue", "yellow"))
1 <- list(numbers_vec = vec, numbers_mat = mat, colors = fac)

## $numbers_vec
## [1] 1 2 3 4 5 6 7 8 9 10
##
## $numbers_mat
## [,1] [,2]
## [1,] 1 6</pre>
```

```
## [3,] 3 8
## [4,] 4 9
## [5,] 5 10
##
## $colors
## [1] blue red blue yellow
## Levels: blue red yellow
```

## Subsetting

- L [ [ 2 ] ]
   Secend element
- L [ 2 ]
   New list with only secend element
- L \$ xElement named x
- L [ 'x ']
   New list with only element named x

#### 1[[2]]

```
## [,1] [,2]
## [1,] 1 6
## [2,] 2 7
## [3,] 3 8
## [4,] 4 9
## [5,] 5 10
```

#### 1[2]

```
## $numbers_mat
## [,1] [,2]
## [1,] 1 6
## [2,] 2 7
## [3,] 3 8
## [4,] 4 9
## [5,] 5 10
```

#### 1\$colors

```
## [1] blue red blue yellow
## Levels: blue red yellow
```

#### 1['colors']

```
## $colors
## [1] blue red blue yellow
## Levels: blue red yellow
```

## Converting

You can convert data structures to each other by functions.

as.vector() as.factor() as.matrix() as.data.frame() as.list()

```
df \leftarrow data.frame(col_1 = c(1:3),
      col_2 = c(4:6)
df
## col_1 col_2
## 1 1 4
## 2 2 5
## 3 3 6
mat <- as.matrix(df)</pre>
mat
## col_1 col_2
## [1,] 1 4
## [2,] 2 5
## [3,] 3 6
1 <- as.list(mat)</pre>
## [[1]]
## [1] 1
##
## [[2]]
## [1] 2
##
## [[3]]
## [1] 3
##
## [[4]]
## [1] 4
## [[5]]
## [1] 5
##
## [[6]]
## [1] 6
vec_mat <- as.vector(mat)</pre>
vec_mat
## [1] 1 2 3 4 5 6
fac <- as.factor(vec_mat)</pre>
## [1] 1 2 3 4 5 6
## Levels: 1 2 3 4 5 6
```

```
df <- as.data.frame(1)
df</pre>
```

```
## X1L X2L X3L X4L X5L X6L ## 1 1 2 3 4 5 6
```

**Q\_1:** When we convert a data frame or a matrix to a list, we miss the column names. Is it possible to assign the column names to the list elements?

Yes, you can use the names().

```
names(1) <- colnames(mat)
1</pre>
```

```
## $col_1
## [1] 1
##
## $col_2
## [1] 2
##
## $<NA>
## [1] 3
##
## $<NA>
## [1] 4
##
## $<NA>
## [1] 5
##
## $<NA>
## [1] 6
```

However, you cannot assign the column names directly. It cannot recognise the elements of each column. So we need to define the names by ourselves.

```
names(1) <- rep(colnames(mat), each = 3)
1</pre>
```

```
## $col_1
## [1] 1
##
## $col_1
## [1] 2
##
## $col_1
## [1] 3
##
## $col_2
## [1] 4
##
## $col_2
## [1] 5
```

```
## $col_2
## [1] 6
```

**Q\_2:** Is it possible to convert any type of object to another?

No, sometimes converting two-dimensional data structures to single-dimensional data structures is impossible. For example, you cannot convert a data frame or a list to a vector.

```
vec_df <- as.vector(df)</pre>
vec_df
## $X1L
## [1] 1
##
## $X2L
## [1] 2
##
## $X3L
## [1] 3
##
## $X4L
## [1] 4
##
## $X5L
## [1] 5
##
## $X6L
## [1] 6
vec_l <- as.vector(1)</pre>
vec_l
## $col_1
## [1] 1
##
## $col_1
## [1] 2
##
## $col_1
## [1] 3
##
## $col_2
## [1] 4
##
## $col_2
## [1] 5
##
## $col_2
## [1] 6
```

## **Make Functions**

You can write your own functions to make repetitive operations using a single command. Your function can return nothing and should be defined before use.

```
function_name <- function(argument1 , argument2,...) {
    Do Something
    return(output)
}</pre>
```

```
# I want to write a function to add two numbers and check if their addition is more than 10. I want to
check_more_than_10 <- function(num1, num2){
   if (num1 + num2 > 10){
      return("Yes!")
   } else {
      return("No!")
   }
}
```

## [1] "No!"

# Naming Objects and Functions

- Object names must start with a letter, and can only contain letters, numbers, underscore (\_), and dot (.).
- The name of an object should be meaningful and show its purpose clearly.
- There are different styles of naming objects, but it is recommended to use the snake\_case style. In this style, each space is replaced by an underscore character, and the first letter of each word is written in lowercase.
- There are other ways to name objects. someUseUpperLettersToSeparateWords some.use.dots

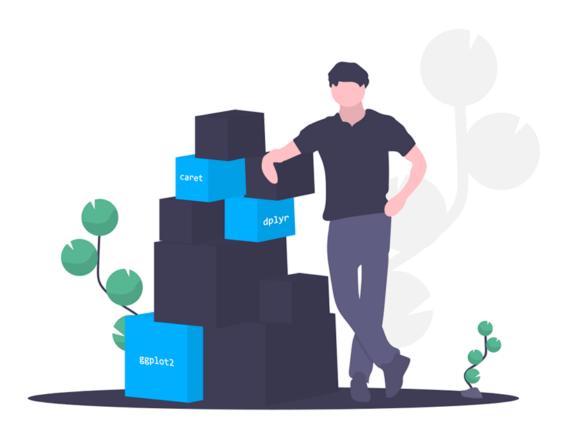

Here are some tips for naming objects:

- Show what type of data structure your object is. For example, cars\_df shows this object is a data frame.
- Start the name of logical variables with "is". For example, is\_odd = TRUE.

- Sometimes, you have to use a string or a number several times. For instance, you have a not ordered vector of numbers. You want to select numbers more than 10, but you are unsure if you want to change them later, and you used this condition many times in your code. It is better to define this value as a variable. Because if you decide to change the value, you don't need to change it one by one. You will change the value. It is better to name it will all uppercase letters. Like SELECTED\_NUMS = 10.
- Names should be meaningful, but you should not name them long. For instance, besides naming this: up\_regulated\_genes\_from\_gsea\_method\_and\_mesh\_database\_list

  Use this: up\_gsea\_mesh\_1
- Start function names with command verbs to separate them from other objects and variables.
- There are some reserved names in R. We call them keywords. For example, data frame is a key word. You cannot name your objects similar to a reserved name. Because they will be overwritten and you will miss them.
- Have your own style in naming!

# Libraries and Packages

In R, a package is a collection of R functions and data. Packages are stored in libraries. The tidyverse package is a collection of R packages designed for data science.

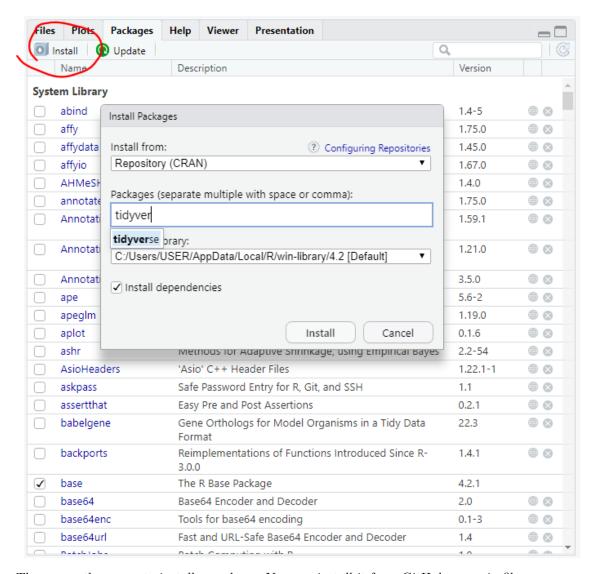

With library(), we can load the packages into the session and make their functions available.

```
# install.packages("tidyverse)
library(tidyverse)
## -- Attaching packages --
                                          ----- tidyverse 1.3.2 --
## v ggplot2 3.3.6
                    v purrr
                             0.3.4
                             1.0.9
## v tibble 3.1.8
                    v dplyr
## v tidyr
           1.2.0
                    v stringr 1.4.0
## v readr
           2.1.2
                    v forcats 0.5.1
## -- Conflicts ----- tidyverse_conflicts() --
## x dplyr::filter() masks stats::filter()
## x dplyr::lag()
                  masks stats::lag()
library(tidyverse)
```

You can see some packages are loaded. But the loading message is followed by a message that some functions are masked. Because some of the functions have the same name in different packages. For example, both stats and dplyr have a function called filter. To determine which package you want to use, you can write it in this format: dplyr::filter().

CRAN is a network of web servers around the world that store identical versions of code and documentation for R. You can install packages from CRAN by running install.packages("package\_name"). However, you can install a CRAN package from the right panel of RStudio.

There are other ways to install a package. You can install it from GitHub or a .zip file on your computer.

You can install that package with this command:

install.packages("file\_path\\package\_file\_name.extension", repos = NULL, type = "source")
Or, in the previous window, change the "install from" to Package Archive File.

You can install a package from GitHub. First, you need to install the devtools package.

install.packages(devtools)

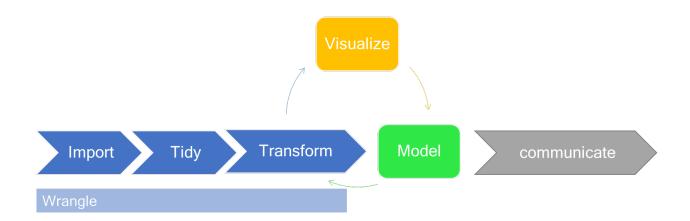

Then you can use this command:

devtools::install\_github(account\_name/repository\_name)

# **Data Wrangling**

Data wrangling - data cleaning - refers to various processes designed to transform raw data.

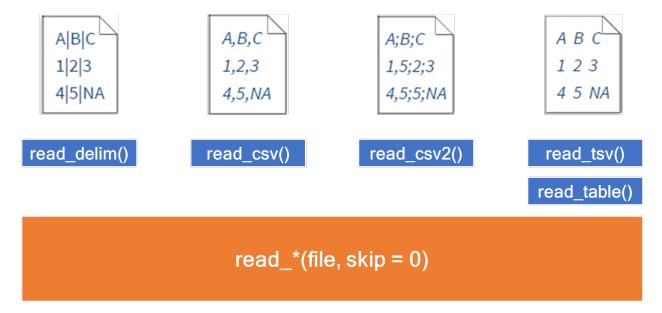

There are three main parts to data wrangling:

### **Importing Data**

We use the readr package to import data. There are four types of files.

- delimited file: A delimited file is a sequential file with column delimiters.
- CSV file: A CSV (comma-separated values) file is a text file in which commas or semicolons separate information.
- TSV file: A TSV file is a tab-separated values file for storing data in a tabular structure.

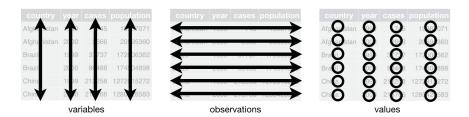

You can read files from excel with functions from readxl package. my\_data <- readxl::read\_excel("my\_file.xls")
You can specify a sheet by its name or index. my\_data <- read\_excel("my\_file.xlsx", sheet = 2)
my\_data <- read\_excel("my\_file.xlsx", sheet = "name\_of\_sheet")

## Tidy Data

Tidy data is a consistent way of storing data that makes the next steps easier. There are three rules which make a dataset tidy:

- 1. Each variable must have its own column.
- 2. Each observation must have its own row.
- 3. Each value must have its own cell.

We have a file in the "Sessions/1/data/" containing tidy data from some women about their living place, height and weight.

```
women <- readr::read_csv("data/women.csv")

## Rows: 15 Columns: 4

## -- Column specification ------

## Delimiter: ","

## chr (2): name, city_province

## dbl (2): weight_kg, height_cm

##

## i Use 'spec()' to retrieve the full column specification for this data.

## i Specify the column types or set 'show_col_types = FALSE' to quiet this message.</pre>
```

## Transformation

We will learn some functions that help transform our data.

### mutate()

The mutate() adds new variables and preserves existing ones. Syntax: mutate(data.frame, new\_column\_1 = calculation\_1, new\_column\_2 = calculation\_2, ...)

```
women <- mutate(women, height_inch = height_cm / 2.54)
women</pre>
```

```
## # A tibble: 15 x 5
##
      name
                city_province weight_kg height_cm height_inch
                 <chr>
##
      <chr>
                                    <dbl>
                                              <dbl>
                                                           <dbl>

## 15 Eleanor
                Ottawa, ON
                                     72
                                             32.7
                                                         164
                                                                    64.6
```

#### ifelse()

The ifelse() is a shorthand vectorised alternative to the standard if...else statement. Syntax: ifelse(test\_expression, x, y)

```
num_vec <- c(1:10)
result <- ifelse( num_vec %% 2 == 0, "even", "odd" )
names(result) <- c(1:10)
result</pre>
```

```
## 1 2 3 4 5 6 7 8 9 10
## "odd" "even" "odd" "even" "odd" "even" "odd" "even"
```

You can use it with mutate().

#### case\_when()

The case\_when() is an alternative to an ifelse(). You can use multiple if else statements whenever you need to use them. Syntax: case\_when(conditional\_statement1  $\sim$  x, conditional\_statement2  $\sim$  y, ...)

```
num_vec <- c(0:10)
result <- case_when(num_vec == 0 ~ "zero",
                     num_vec %% 2 == 0 ~ "even",
                     TRUE ~ "odd") # TRUE means if not all above conditions are equal to TRUE, so set "o
names(result) \leftarrow c(0:10)
result
                       2
                               3
                                              5
                                                             7
        0
                                      4
                                                     6
                                                                            9
                                                                                  10
                1
                                                                    8
           "odd" "even"
                          "odd" "even"
                                         "odd" "even"
                                                        "odd" "even"
                                                                        "odd" "even"
```

You can use it with mutate().

```

## # ... with abbreviated variable names 1: weight_kg, 2: weight_kg_mean,
       3: weight_lbs, 4: height_cm, 5: height_inch, 6: is_bmi_normal
```

Q1: Why are the results different? Because calculating the mean in grouped data frame equals to mean in each group, but in ungrouped data.frame equals to mean of all weights.

You can ungroup data with ungroup(data).

```
women <- ungroup(women_g)</pre>
```

**Q2:** Is it possible to group data based on different variables? It is not possible with group\_by(). You can add a new column that shows the results of performed conditions and use that for group\_by().

#### subset()

The subset() returns a subset of the object which meets conditions.

Syntax: subset (x, subset\_sondition)

```
women_tall <- subset(women, bmi == "normal")
women_tall</pre>
```

```

#### distinct()

The distinct selects only unique rows from a data frame. It picks the first represented duplicate row.

Syntax: distinct(df, column1, column2, ..., .keep\_all) Always set .keep\_all to TRUE.

Here is the new table. Three names are not unique.

```

#### separate\_rows()

"If a variable contains observations with multiple delimited values, this separates the values and places each in its own row." Here, the city\_province column values are delimited by a comma.

Syntax: separate\_rows(data, col,  $\dots$ , sep, convert, remove) The convert should be a logical value. Always set it to TRUE.

```
women_sep_row <- separate_rows(women, city_province, sep = ",", convert = TRUE)</pre>
```

#### separate()

The separate() turns a single character column into multiple columns.

Syntax: separate(data, col, into, sep, convert). The convert should be a logical value. Always set it to TRUE.

```
women_sep_col <- separate(data = women, col = city_province, into = c("city", "province"), sep = ",", c
women_sep_col</pre>
```

```

rownames_to_column()

The rownames_to_column() convert rownames to a column.
Syntax: rownames_to_column(data, var)
```

## Strings

We will discuss some points and functions to work with strings in R.

women <- tibble::rownames\_to\_column(women, var = "name")</pre>

#### **Functions**

- paste(x, y, sep = ' ')
   Join multiple strings together
- paste0(x, y)
   Join multiple vectors together with no space between them.
- paste(x, collapse = ' ')
   Join elements of a vector together.

- gsub(pattern, replace, x)
   Replace matches in x with a
   string.
- grep(pattern, x)
   Find regular expression matches in x.
- toupper(x)
   Convert to uppercase
- tolower(x)
   Convert to lowercase.
- str\_to\_title()
   convert the first letter of every word of a string to Uppercase and the
   rest of the letters are converted to lower case.

```
str_1 <- "Hello_"
str_2 <- "World!"
vec <- c(str_1, str_2)
# paste
paste(str_1, str_2, sep = " ")

## [1] "Hello_ World!"

paste(vec, collapse = " ")

## [1] "Hello_ World!"</pre>
```

```
pasteO(str_1, str_2)
## [1] "Hello_World!"
# gsub
gsub("_", "!", str_1)
## [1] "Hello!"
grep("Wo", vec)
## [1] 2
# to
toupper(str_2)
## [1] "WORLD!"
tolower(str_1)
## [1] "hello_"
# str_to_title
str_to_title("r workshop")
## [1] "R Workshop"
```

#### **Special Characters**

The "\" is a special character in R. If you want to type a slash, you need to put another slash before it. Also, if you want a quotation in your string, you need to put a slash before it.

(Read the stringr cheatsheet second page for more information.)

```
# print("\") ##You will get an error!
slash <- "\\"
slash
## [1] "\\"

# Acknowledgement

I would like to thank my supervisor Dr Gregor Reid, Dr Ali Farrokhi, and Tanmaya Atre, for their support and guidance. Also, I would like to thank Reid's lab members and all of the people who helped me to get through my project.
